Sample Questions and Model Answers from April 2014 Unit 3B

Below are examples of typical questions from the April 2014 exam, along with strategies for approaching them.

Example 1: Enthalpy Calculations

Question:

Calculate the standard enthalpy change of formation of methane, CH_4 , given the following data:

- Combustion of methane: $\text{CH}_4(\text{g}) + 2\text{O}_2(\text{g}) \rightarrow \text{CO}_2(\text{g}) + 2\text{H}_2\text{O}(\text{l})$ $\Delta H = -890 \text{ kJ}$
- Combustion of carbon: $\text{C}(\text{s}) + \text{O}_2(\text{g}) \rightarrow \text{CO}_2(\text{g})$ $\Delta H = -393 \text{ kJ}$
- Formation of water: $\text{H}_2(\text{g}) + \frac{1}{2}\text{O}_2(\text{g}) \rightarrow \text{H}_2\text{O}(\text{l})$ $\Delta H = -285.8 \text{ kJ}$

Model Answer:

Using Hess's Law, rearranged to find the formation of CH_4 :

- Write the target reaction:

- Combine given reactions:

- Combustion of methane (given)
- Reverse combustion of carbon to produce elemental carbon
- Use the formation of water to account for hydrogen

- Calculate:

$$\Delta H_f(\text{CH}_4) = [\Delta H_{\text{combustion of C}} + 2 \times \Delta H_{\text{formation of H}_2\text{O}}] - \Delta H_{\text{combustion of CH}_4}$$

But more straightforwardly, applying Hess's Law:

$$\Delta H_f(\text{CH}_4) = [\Delta H_{\text{combustion of CH}_4}] - [\Delta H_{\text{combustion of C}}] - 2 \times [\Delta H_{\text{formation of H}_2\text{O}}]$$

$$= (-890) - (-393) - 2 \times (-285.8)$$

$$= (-890 + 393 + 571.6) = 74.6 \text{ kJ}$$

Note: The calculated enthalpy change indicates the energy required to form methane from its elements.

Example 2: Cell Potential Calculation

Question:

Given the standard electrode potentials:

- $\text{Fe}^{3+} + \text{e}^- \rightarrow \text{Fe}^{2+}$; $E^\circ = +0.77 \text{ V}$
- $\text{Fe}^{2+} + 2\text{e}^- \rightarrow \text{Fe}$; $E^\circ = -0.44 \text{ V}$

Calculate the standard potential for the overall reaction:

Model Answer:

Step 1: Write the half-reactions and identify oxidation and reduction:

- Reduction: $\text{Fe}^{3+} + \text{e}^- \rightarrow \text{Fe}^{2+}$ ($E^\circ = +0.77 \text{ V}$)
- Reduction: $\text{Fe}^{2+} + 2\text{e}^- \rightarrow \text{Fe}$ ($E^\circ = -0.44 \text{ V}$) (which is actually a reduction, but since E° is

negative, it favors oxidation)

Step 2: Reverse the second reaction to find oxidation:

Step 3: Multiply the reactions to balance electrons:

- The first reduction involves 1 e^{-}
- The second (oxidation) involves 2 e^{-}

Multiply the first reaction by 2 to match electrons:

Now, combine with the oxidation:

Add the two:

But this simplifies to:

Step 4: Write the overall reaction:

The overall cell potential (E°) is calculated as:

$$E^{\circ} = E^{\circ}(\text{cathode}) - E^{\circ}(\text{anode})$$

Here, the cathode is $\text{Fe}^{3+}/\text{Fe}^{2+}$ ($E^{\circ} = +0.77 \text{ V}$), and the anode is Fe/Fe^{2+} ($E^{\circ} = -0.44 \text{ V}$). Therefore:

$$E^{\circ} = +0.77 \text{ V} - (-0.44 \text{ V}) = +1.21 \text{ V}$$

Final Answer:

The standard potential for $\text{Fe}^{3+} + 3\text{e}^{-} \rightarrow \text{Fe}$ is +1.21 V.

Question What are the key differences between spectroscopic and chromatographic techniques in instrumental analysis? Spectroscopic techniques involve measuring the interaction of electromagnetic radiation with matter to identify or quantify substances, while chromatographic techniques separate components of a mixture based on their distribution between a stationary and a mobile phase. Both are essential but serve different purposes in analysis. How can calibration curves be used to determine the concentration of an analyte in a sample? Calibration curves are constructed by plotting known concentrations of an analyte against their measured instrument responses. By measuring the response of an unknown sample, its concentration can be interpolated from the calibration curve, ensuring accurate quantification. What are common sources of error in instrumental analysis, and how can they be minimized? Common sources include instrument drift, sample contamination, improper calibration, and environmental factors. Minimization strategies involve regular calibration, proper sample preparation, maintaining equipment, and controlling environmental conditions. Explain the principle of Beer-Lambert Law and its application in spectrophotometry. The Beer-Lambert Law states that absorbance is directly proportional to concentration and path length ($A = \epsilon cl$). It is used in spectrophotometry to determine analyte concentration by measuring absorbance at specific wavelengths. What are the advantages and limitations of atomic absorption spectroscopy (AAS)? Advantages include high sensitivity, selectivity for metals, and relatively simple operation. Limitations involve the restriction to metal analysis, sample preparation requirements, and potential interference from other ions. How does mass spectrometry complement other instrumental techniques in analysis? Mass spectrometry provides molecular weight and structural information, enabling precise identification of compounds. It often complements techniques like chromatography by confirming compound identity and purity. What considerations should be taken into account when selecting an instrumental technique for an analysis? Factors include the nature of the sample, required sensitivity and specificity, the analyte's physical and chemical properties, available equipment, cost, and the purpose of the analysis (qualitative or quantitative).
